2043. Simple Bank System

You have been tasked with writing a program for a popular bank that will automate all its incoming transactions (transfer, deposit, and withdraw). The bank has n accounts numbered from 1 to n . The initial balance of each account is stored in a **0-indexed** integer array `balance`, with the $(i + 1)^{\text{th}}$ account having an initial balance of `balance[i]`.

Execute all the **valid** transactions. A transaction is **valid** if:

- The given account number(s) are between 1 and n , and
- The amount of money withdrawn or transferred from is **less than or equal** to the balance of the account.

Implement the `Bank` class:

- `Bank(long[] balance)` Initializes the object with the **0-indexed** integer array `balance`.
- `boolean transfer(int account1, int account2, long money)` Transfers money dollars from the account numbered `account1` to the account numbered `account2`. Return `true` if the transaction was successful, `false` otherwise.
- `boolean deposit(int account, long money)` Deposit money dollars into the account numbered `account`. Return `true` if the transaction was successful, `false` otherwise.
- `boolean withdraw(int account, long money)` Withdraw money dollars from the account numbered `account`. Return `true` if the transaction was successful, `false` otherwise.

Example 1:

Input
["Bank", "withdraw", "transfer", "deposit", "transfer", "withdraw"]
[[[10, 100, 20, 50, 30]], [3, 10], [5, 1, 20], [5, 20], [3, 4, 15], [10, 50]]

Output
[null, true, true, true, false, false]

Explanation
`Bank bank = new Bank([10, 100, 20, 50, 30]);`
`bank.withdraw(3, 10);` // return true, account 3 has a balance of \$20, so it is valid to withdraw \$10.
// Account 3 has \$20 - \$10 = \$10.
`bank.transfer(5, 1, 20);` // return true, account 5 has a balance of \$30, so it is valid to transfer \$20.
// Account 5 has \$30 - \$20 = \$10, and account 1 has \$10 + \$20 = \$30.
`bank.deposit(5, 20);` // return true, it is valid to deposit \$20 to account 5.
// Account 5 has \$10 + \$20 = \$30.
`bank.transfer(3, 4, 15);` // return false, the current balance of account 3 is \$10, // so it is invalid to transfer \$15 from it.
`bank.withdraw(10, 50);` // return false, it is invalid because account 10 does not exist.

Constraints:

- $n == \text{balance.length}$
- $1 \leq n, \text{account}, \text{account1}, \text{account2} \leq 10^5$
- $0 \leq \text{balance}[i], \text{money} \leq 10^{12}$
- At most 10^4 calls will be made to **each** function `transfer`, `deposit`, `withdraw`.
